The best you could probably do is change your function to take an extra parameter which is a constructor function for type `T` and use that to do the `instanceof` :

```
class Foo {
  public blah() {
  }
}

function success<T>(check:T|boolean, constructor:{new ():T}):boolean {
  return typeof check === 'boolean' ? check : check instanceof constructor;
}

success<Foo>(new Foo, Foo);
```

@ken-blocklevel You can do `T extends Object` , but you still can't do an `instanceof` without a constructor function for `T` .
